LAMPROTHAMNIUM PAPULOSUM (WALLR.) J. GROVES, A THREATENED CHAROPHYTE IN SCANDINAVIA

Irmgard BLINDOW and Anders LANGANGEN

¹Department of Ecology/Limnology, Ecology Building, S-223 62 Lund, Sweden ² Hallagerbakken 82 b,1256 Osto, Norway

ABSTRACT - The distribution of Lamprothermium paparlosum in Scandinavia is presented in this paper. There has been a marked decline in the occurrence of the species, most probably due to eutrophication and urbanisation of the localities in question. The number of localities left approximally small, and the authors group the species under the category endangered species Necessary steps should be taken to protect the species by law, and its distribution in Scandinavia should be further investigated.

RESUMÉ. - La distribution de Lamprothammian papulosum en Scandinavie est présentée. Cette espèce a subt un déclin marqué dont la raison est três probablement l'eutrophication et l'urbanisation des localités d'où elle a dispara. Le nombre de localités où elle est encore présente est faible et les auteurs placent ce taxon partii les espèces en danger. Des mesures légales nécessaires à sa protection doivent être prièse et l'étaide de sa distribution en Scandinava dont être poursaives.

KEY WORDS: Lamprothamnium papulosum, Charophytes, Scandinavia, threatened species.

INTRODUCTION

The old name Chara alopecuroides given to this taxon by Wallmann (1833) is the basis for its popular name, «foxtail stonewort». As this species differs from other members of the genus Chara by having the antheridium above the oogonium. Leonhardi (1863) placed it into a new genus Dychnothannus. Later the name was changed to Lamprothannus (forces, 1916). Because an old epithet, papulosum, given to the taxon by Wallroth (1833), had priority, the taxon is now called Lamprothannium papulosum. Other details concerning the nomenclature and taxonomy of this species can be found in Daniel (1975).

SHORT DESCRIPTION OF THE SPECIES

Stem slender, up to 30 cm high (Fig. 1). Cortex absent. Stipulodes long, in one row. Monoecious. Oogonium below the antheridium. Bulblis of *Chara aspera* type, white, spherical, up to I min in diameter (McNicol, 1907).

Figure 1. - Lamprothamnium papulosum. Photo of a specimen collected 31.08.1994 in Kalvöfjorden, Sweden. The length of this plant is c. 5 cm.

ECOLOGY

Lamprothamnium papulosum is only found in brackish water (Daniel, 1975; Moore, 1986). Observations and experiments on its tolerance to salinity have been done by Dubois (1968); Daniel (1975); Bisson & Kirst (1980); Wichmann & Kirst (1989) and others.

The species can tolerate great variations in salinity. Daniel (1975) has shown experimentally that it grows best in the range \$8%-28%. In the Baltic Sea, the species has been found between the isohalines of 8% and 18% (Olsen, 1944). Old plants can survive even greater variation in salinity (Wichmann & Kirst, 1989). Germination of the cospores is optimal at a salinity of 10% (Dobois, 1968).

In Scandinavia, Lamprothamnium occurs in sheltered bays and brackish water lagoons in the Skagerak and the western part of the Baltic Sea (Olsen, 1944) (Fig. 2).

The alga is most often found on sand/silt bottom in shallow water down to a depth of $1\text{-}2\ \text{m}$.

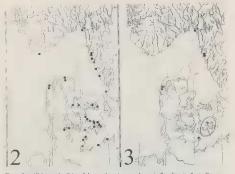

Figure 2. - All known localities of *Lamprothamnium papulosum* in Scandinavia. Some German localities are also added.

Figure 3. - All known localities of Lamprothamnium papulosum in Scandinavia after 1983. Circle: Area with several localities (Andersson, pers. comm).

BIOLOGICAL DEVELOPMENT

L. papulosum is normally richly fertile and survives the winter by oospores or bulbils. In Norway, the oospores are mature from August (Langangen, 1974).

DISTRIBUTION IN NORTHERN EUROPE

Lamprothamnium papulosum has been found in some localities on the Baltic coast of Germany (Sonder, 1890; Migula, 1897). The distribution in Britain and Ireland was given by Stewart & Church (1992). A map of the European distribution can be found in Corillion (1957, map 36).

In Scandinavia, Lamprothamnium paqualosum was found in a number of localities (Fig. 2.) along the coasts of the Skagerak and the Baltic Sea (Hassiow, 1934; Tecan localities: see below). Only a few localities are known for the time after 1983 (Fig. 3); these localities are described in detail below.

THE NORWEGIAN LOCALITIES

From the following two localities, Lamprothamnium papulosum probably has disappeared. Both localities are clearly eutrophicated.

- Vest-Agder: Mandal: Skogsfjord coll. 1881. During 1991 and 1992. L. papulosum was not found; the fjord was filled with Enteromorpha sp. and filamentous algae (own observations, A.L.).
- Østfold: Hvaler: Vauerkilen coll. 1838 and 1969. In subsequent years, the species has not been found (Steen, 1993; own observations, A.L.).
- On the following two localities, Lamprothamnium papulosum was found recently.
- 3. Ostfodi: Hvalier Skipstadkilen (Fig 4), close to the Swedish border is a lagoon covering an area of about 1.5 km² and with a deght of about 1.m. It is mostly surrounded by belts of Scirpus tabernuemontani C.C.Gmel., S. maritimus L. and Phragmites australis (Cav.) Steud and, in the water, Ruppia spp. The inner part of the pond is dominated by charophyse, especially Chara aspera Deth. ex Willd., which grows in dense stands. In openings in these stands specimens of Chara caneezes Devs. eLoss and Tobypella midpice (Miller) A.Br. can be found. In 1969 Lamprochamnium papulosum grew in most parts of the lagoon both in shallow and deeper water (Langangen, 1972). In 1993 it was only found in a few places mostly in the middle of the locality. The specimens were up to 17 cm long, richly fertile and with some ripe. black cospores, Other algae were found, such as Caldaphora sp., Euteromorpha as Rhizaclonium sp. Over the years the salinity ranged from 7% to 13% (own observations, A.L.)

Bharathan & Sundaralingam (1984) used specimens of L. papulosum from Skipstad kilen in their description of the developmental morphology of the species.

4. Østfold: Sorge: Hunnebunnen is an old oyster poll. Klavestad (1957) reported Chara canescens and Tolypella nidificat from this locality. During 1994, a few specimens of Lamprothamnium papulosium were found in the poll: the piants were normally developed and richly fertile. Masses of filamentous algae occurred covering all plants including the charophyses. The salinity was 10 %. (Own observations, A.L.).

THE SWEDISH LOCALITIES

In Sweden, Lamprothamnium papulosum has only been found along the west coast. The following five older records are known:

- Bohuslän: Marstrand coll. 1891, 1892. It is unknown if Lamprothamnium papulosum still occurs; the locality should be revisited.
- Västergötland: Gøteborg 1885. This area is urbanised, and we assume that Lamprothamnium papulosum has disappeared from this locality.
- 3. Halland: Varberg, north of the island Getterön and N.Näs, both coll. 1933. The locality was revisited during 1994, but Lamprothamnium papulosum could not be found (own observations, A.L.). According to Flodin (pers. comm.), the locality has

changed much since 1933, especially in connection with the new road, when the island became # peninsula, and the area was filled up with sediments.

- 4. Halland: Onsiala coll. 1868. Unterström-Gustavsson (1993) visited the area during 1987-1990, but neither during these years nor during a revisit in 1994 (Utterström-Gustavsson, pers. comm), she could find any charophytes. The water was heavily eutrophicated; in later years, the water quality improved after the building of a sewage olant.
- Skåne: Norrviken nearby Båstad coll. 1912. We have no information if Lamprothamnium occur on this locality today.

During the last years Lamprothamnium papulosum was found on the following three localities:

 Bohuslän: Ängholmen on the island of Mjörn (Coll. 1903, 1965 (Pehrsson, 1976). The area was revisited during 1994 (A.L.) (Fig 5).

Small (5.7 cm), well developed specimens grew scattered in shallow water on soft bottom (Fig. 6). All specimens were richly fertile in an early stage of development with the old oospore still attached to the trizoides. Ruppins spp., Zostern marina L. and different filamentous algae (e.g. masses of Cladophora spp.) dominated the submerged vegetation. The locality was clearly eutrophicated.

7. Rohuslin: Kalvofjorden nearby Haga (own observations 1994, I.B.). Lamprothannium papuloisum grew on shallow water (10 cm) together with Ruppia sp., other submerged plants and masses of filamentous algae. The specimens were small (5-7 cm, Fig. 1), well developed, richly fertile with some ripe black oospores. The locality was clearly eutrophicated.

8. Bohuslän: Kalvöfjorden, Råssön close to Hjälmvik, coll. Mokshes 1994, det. I.B. This locality is situated close to the former locality. Different persons observed Lamprothamnium on this locality during 1991-1994. Lamprothamnium was growing on 0,5 m depth together with Zostera sp. and Ruppia sp. (M. Kuylenstierna, pers. comm.)

THE DANISH LOCALITIES

Olsen (1944) reported about 25 localities for Lamprothamuum papulasum in Denmark, most of them from the 1800s. It is unknown how many of these localities still exist, but we assume that Lamprothamulum has decreased also in Denmark. In Vestsjelland, Lamprothamulum has not been refound in areas where the species occurred earlier. The areas in question have been heavily eutrophicated since 1960 (J. Strømberg, Vestsjellands Amt, pers. comm.).

Christensen (pers. comm.) reported that the Limfjorden area has been heavily eutrophicated, and he doubts that Lamprothamnium still exists on its former localities in this area. On the other hand, Lamprothamnium was reported from two new localities in this area (see below).

The present known localities of Lamprothamnium papulosum in Denmark are:

1. Limfjorden, western part (Doverkil nearby Ydby, coll. 1981 T. Christensen). The plants have decreased during the last years probably due to mass growth of Cladophora sp. covering the bottom (T. Christensen, pers. comm.).

 Limfjorden: Nissum Breding (a lagoon by Foliup Odde nearby Lemvig, coll. 1991 T. Christenson).

3. Dybsø Fjord 1983, leg. Werner Krause, herbaria of Copenhagen and Oslo. The specimens are small, 5-7 cm high, and richly fertile. According to Christensen (pers. comm.) masses of free-floating Cladophora sp. now cover the bottom of this fiord.

4. Several localities in the area around Nykøbing, Sjælland for the period 1989-1991 are given by J.Andersson (pers. comm.). The plants are not deposited in any herbarium. The area is marked by a circle (Fig. 3).

THE STATUS OF LAMPROTHAMNIUM PAPULOSUM IN SCANDINAVIA, ITS THREAT AND PROTECTION

In all three countries (Denmark, Norway and Sweden) records of Lamprohomnium papulosum are sparse during the last years. This is partly due to the fact that this species as well as other members of the group of Charophyta often are neglected during investigations of the vegetation. Another reason is that the species has declined during the last decennia. In all countries, Lamprohamnium papulosum could no be refound on several localities where it occurred before. In Sweden, the species was therefore listed as endangered (Blindow, 1994). The same status was given Lamprohamnium papulosum in the German Red List (Krause, 1984), Glowinski (1984) recopred the species from several localities on Fehrman (see Fig. 1864).

Eutophication is the most probable reason for this decline. Mass growth of filamentous algae like Cladophora is reported from many of the polluted areas. These filamentous algae often cover Lamprothamnium totally. Therefore, we assume that competition with other primary producers for light and space is the effective mechanism for the disappearance of Lamprothamnium papulosum during eutrophication. From one locality (Sweden, Varberg) Lamprothamnium disappeared probably due to the construction of a new road.

To protect Lamprothamnium papulosum, the following steps should be taken:

 Most important is the decrease of pollution in the brackish water habitats which are situated within the distribution range of this species. In the future, the construction of sewage water plants may perhaps change the negative trend of this species.

Figure 6. Angholmen, Sweden, Lamprothamnium papulosum (small, darker dots) growing on shallow water in association with other plants. Photo 05.08, 1994 A.L.

- 2. In all Scandinavian countries, the occurrence of Lamprothamnium papulosum should be further investigated, especially on its former localities, its actual localities should be legally protected against destruction.
- The species can be protected by law as was done in Britain in 1987 (Wildlife and Countryside Act 1981).

ACKNOWLEDGEMENT. We are grateful to all persons who contributed with information about the contribute of *Lamprathamatina prapticusss*. id-bin Andersson, Storastrano Ann. Desmark, Professor Type Christensen, Denmark, Ake Flodini, Varberg, Sweden. Dr. Werner Krauc, Cermany, Borks Kuylensteinan, Kristineby, Sweden. Olfo Pelmerson. Grateborg, Sweden. Dr. Werner Krauc, Cermany, Vestajellands Arnt, Denmark, Ullia Unerstrom Gratavasson. Grateborg, Sweden. May real redebard to Dr. Oaker Gattarie (Odslo) who knowledy cornected the English test und to Total Sermensen (Odslo) who holdy cornected the English test und to Total Sermensen (Odslo) who translated the Penech summary. WWF (Sweden) has given financial support to one of set (I.B.) We also obands Curators at the Universities of Copenhagen, Stockshort, Uppstala, Land and Odd.
